Agricultural Implications

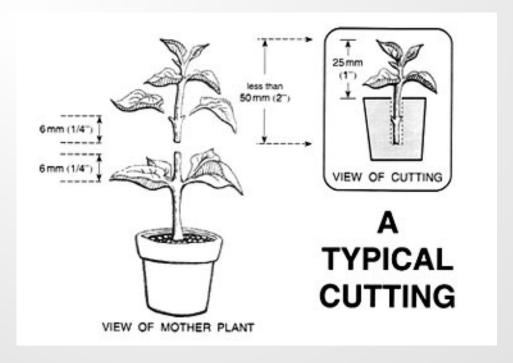

S1-1-04 Investigate and describe agricultural applications of asexual reproduction. Examples: cloning, cuttings, grafting (vegetative propagation), bulbs

Vegetative Propagation:

When a <u>NEW PLANT</u> is grown from a <u>PIECE</u> of another plant. There are several ways a plant can reproduce this way:

CUTTINGS:

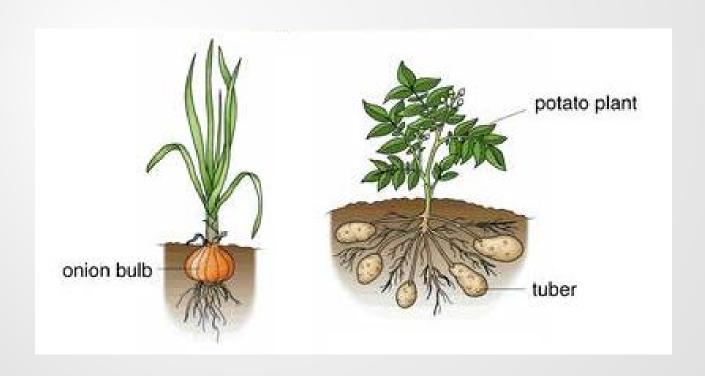

Cut a leafy <u>ROSE STEM</u> and place it into wet <u>SAND/WATER</u>. New <u>ROOTS</u> will grow, creating a <u>NEW PLANT</u>.

Vegetative Propagation:

BULBS:

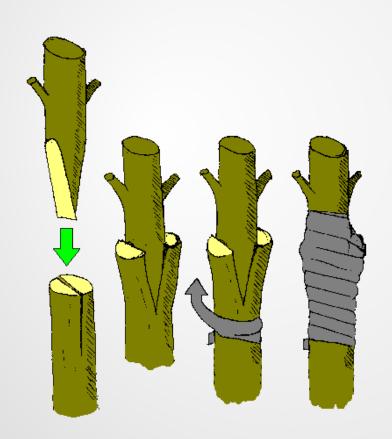

- Are thick, fleshy <u>UNDERGROUND</u> <u>STEMS</u>.
- They have a large store of <u>FOOD</u>, which allow them to survive for a while <u>BEFORE</u> being <u>PLANTED</u>. (<u>ONIONS</u>, <u>TULIPS</u>)

Vegetative Propagation:

GRAFTING:

A <u>BRANCH</u> of one type of plant is placed into the <u>CUT</u> of <u>ANOTHER</u>.
 They must be <u>CLOSELY RELATED</u>. (<u>APPLE TREES</u>, etc)

Cloning

You'll be surprised to hear that cloning is not the "mad science" that you see in the movies. In fact, **CLONES** are around you all the time.

Cloning is a **NATURAL** process by which **MOST** organisms **REPRODUCE**.

In all types of <u>ASEXUAL REPRODUCTION</u>, organisms make <u>EXACT</u> genetic <u>DUPLICATES</u> of themselves, which are essentially clones!

They have the exact same **DNA**.

In cloning, there is only **ONE PARENT**. If there were two, then the offspring wouldhave a combination of DNA from each parent.

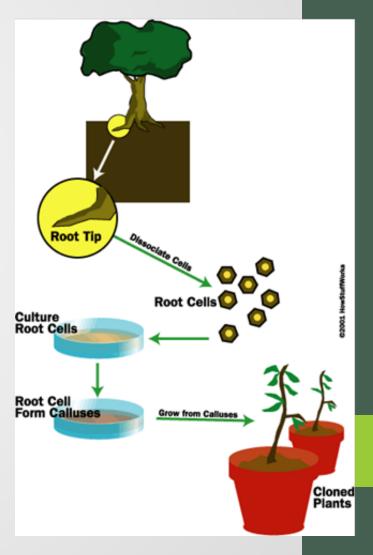

Hence, <u>ASEXUAL</u> <u>REPRODUCTION</u> produces **CLONES**.

Cloning a Plant From a Single Cell:

In 1958, Frederic Stewart cloned a <u>CARROT</u>. He took a cell from the <u>ROOT</u> of the <u>PARENT</u> carrot, and grew a "<u>CLONE</u>" from it.

Today, plants are bred with desired <u>TRAITS</u>, and are then <u>CLONED</u> to keep <u>REPRODUCING</u> these <u>TRAITS</u>

Examples of this are **SEEDLESS WATERMELONS**, **ORANGES**, different varieties of **FLOWERS**, etc.

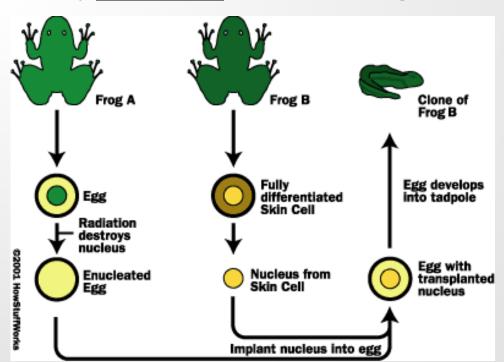

In fact, some animals have even been cloned...

How a Frog Was Cloned

In the 1970s, a scientist named John Gurdon successfully cloned **TADPOLES**.

- He <u>TRANSPLANTED</u> the <u>NUCLEUS</u> from a <u>SPECIALIZED</u> skin cell of one frog into an <u>UNFERTILIZED</u> <u>EGG</u> of another frog in which the <u>NUCLEUS</u> had been <u>DESTROYED</u> by <u>UV LIGHT</u>.
- The egg with the <u>TRANSPLANTED</u> nucleus developed into a <u>TADPOLE</u> that was genetically <u>IDENTICAL</u> to the first frog.

The "Dolly" Revolution

Scientists later cloned an adult sheep. The clone was called Dolly.

How Dolly Was Cloned:

- Cells from the <u>UDDER</u> of a <u>FINN DORSET SHEEP</u> were taken.
- The <u>NUCLEUS</u> was taken out and then placed in an <u>ENUCLEATED</u> <u>EGG</u>
 <u>CELL</u> of another sheep.
- The new cell was placed into a <u>BLACKFACE</u> <u>SHEEP</u>...which gave birth to <u>DOLLY</u>, a <u>CLONE</u> of the <u>FINN</u> <u>DORSET</u>.
