

Outcome:

- Outline the transformation of alkanes to alkenes and vice versa.
- Name, Draw and construct molecular models of alkenes and branched alkenes.

 Compounds formed from <u>CHAINS</u> of carbon atoms that have <u>ONE</u> or <u>MORE DOUBLE BONDS.</u>

- Notice that there is a relationship between the number of carbons and hydrogens...
 - They have the general formula

<u>**C**</u><u>n</u><u>**H**</u><u>2n</u>

- Also called <u>UNSATURATED HYDROCARBONS</u> (DOUBLE BONDS).
- Are also <u>ALIPHATIC</u> <u>HYDROCARBONS</u>.

Naming Alkenes:

- All alkenes end in "<u>ENE</u>"
- Same rules as for Alkanes, but the <u>NUMBERING</u> starts at the end <u>CLOSEST</u> to the <u>DOUBLE BOND</u> (double bond gets the <u>LOWEST</u> possible number).

Examples:

Naming Alkenes:

When MULTIPLE DOUBLE BONDS are present, we use the PREFIXES DI, TRI, TETRA, etc., followed by "ENE" (ex. DIENE)

Examples:

1,3-pentadiene penta-1,3-diene

Naming Alkenes:

When an the chain is in a **<u>RING SHAPED STRUCTURE</u>**, we use the prefix "<u>CYCLO</u>"

Examples:

cyclo butene

X

1,3 Cyclo hexadiene

Reactions of Alkenes

Dehydrogenation

- **<u>REMOVAL</u>** of <u>HYDROGENS</u> through a complex reaction.
- We can dehydrogenate <u>ALKANES</u> to make <u>ALKENES</u>:

Reactions of Alkenes

Hydrogenation

- <u>ADDITION</u> of <u>HYDROGENS</u> in the presence of a <u>CATALYST</u> such as <u>PALLADIUM, PLATINUM OR NICKEL</u>
- Also called an <u>ADDITION REACTION</u> or <u>CATALYTIC HYDROGENATION.</u>
- We can hydrogenate <u>ALKENES</u> to make <u>ALKANES</u>:
